Entrez PubMed	Diversity among the beta subunits of heterotrimeric GTP-binding proteins: characterization of a novel beta-subunit cDNA.
	von Weizsacker E, Strathmann MP, Simon MI.
PubMed	Institut fur Entwicklungsbiologie, Universitat Koln, FRG.
Related Resources	Heterotrimeric guanine nucleotide binding proteins transduce signals from cell surface receptors to intracellular effectors. The alpha subunit is believed to confer receptor and effector specificity on the G protein. This role is reflected in the diversity of genes that encode these subunits. The beta and gamma subunits are thought to have a more passive role in G protein function; biochemical data suggests that beta-gamma dimers are shared among the alpha subunits. However, there is growing evidence for active participation of beta-gamma dimers in some G protein mediated signaling systems. To further investigate this role, we examined the diversity of the beta subunit family in mouse. Using the polymerase chain reaction, we uncovered a new member of this family, G beta 4, which is expressed at widely varying levels in a variety of tissues. The predicted amino acid sequence of G beta 4 is 79% to 89% identical to the three previously known beta subunits. The diversity of beta gene products may be an important corollary to the functional diversity of G proteins. PMID: 1543505 [PubMed - indexed for MEDLINE]

Entrez PubMed	The G protein beta 2 complementary DNA encodes the beta 35 subunit.
	Gao B, Mumby S, Gilman AG.
PubNed Services	Department of Pharmacology, Southwestern Graduate School, University of Texas Health Science Center at Dallas 75235.
	Antisera were generated against synthetic peptides that correspond to amino acid sequences deduced from a cDNA (designated beta 2) that encodes a second form of the beta subunit of guanine nucleotide-binding regulatory proteins (G proteins). The specificity of interactions of these antisera with purified G protein beta subunits indicates that the beta 2 cDNA encodes the beta 35 form of this polypeptide. This hypothesis is confirmed by the use of these antisera to detect expression of the beta 2 cDNA in COS-m6 cells.

Entrez PubMed	Type-specific regulation of adenylyl cyclase by G protein beta gamma subunits.
	Tang WJ, Gilman AG.
PubMed Services	Pharmacology, University of Texas Southwestern Medical Center, Dallas 75235. Heterotrimeric guanine nucleotide-binding regulatory proteins (G proteins) dissociate into guanosine triphosphate (GTP)-bound alpha subunits and a complex of beta and gamma subunits after interaction with receptors. The GTP-alpha subunit complex activates appropriate effectors, such as adenylyl cyclase, retinal subunit complex activates appropriate effectors, such as adenylyl cyclase, retinal phosphodiesterase, phospholipase C, and ion channels. G protein beta gamma
Related Resources	phosphodiesterase, phospholipase C, and ion channels. G protein of growing subunits have been found to have regulatory effects on certain types of adenylyl cyclase. In the presence of Gs alpha, the alpha subunit of the G protein that activates adenylyl cyclase, one form of adenylyl cyclase was inhibited by beta gamma, some forms were activated by beta gamma, and some forms were not affected by beta gamma. These interactions suggest mechanisms for communication between distinct signal-transducing pathways.

The GTP-binding regulatory proteins (G proteins) that transduce signals from receptors to effectors are composed of alpha, beta, and gamma subunits. Whereas the role of alpha subunits in directly regulating effector activity is widely accepted, it has recently been demonstrated that beta gamma subunits may also directly regulate effector activity. This has made clear the importance of identifying and characterizing beta and gamma subunits. We have isolated a cDNA clone encoding a new gamma subunit, referred to here as the gamma 7 subunit, using probes based on peptide sequences of a gamma subunit previously purified from bovine brain. The clone contains a 1.47-kilobase cDNA insert, which includes an open reading frame of 204 base pairs that predicts a 68-amino acid polypeptide with a calculated M(r) of 7553. The predicted protein shares amino acid identities with the other known gamma subunits, ranging from 38 to 68%. Also characteristic of gamma subunits is a carboxyl-terminal CAAX motif. The expression of the gamma 7 subunit as well as the gamma 2, gamma 3, and gamma 5 subunits was examined in several bovine tissues at both the mRNA and protein levels. Whereas the gamma 2 and gamma 3 subunits were selectively expressed in brain, the gamma 5 and gamma 7 subunits were expressed in a variety of tissues. Thus, the gamma 5 and gamma 7 subunits are the first G protein gamma subunits known that could participate in the regulation of widely distributed signal transduction pathways.

Entrez PubMed	A bitter substance induces a rise in intracellular calcium in a subpopulation of rat taste cells.
	Akabas MH, Dodd J, Al-Awqati Q.
Publ/Med Services	Department of Medicine, College of Physicians and Surgeons, Columbia University, New York, NY 10032.
Related	The sense of taste permits animals to discriminate between foods that are safe and those that are toxic. Because most poisonous plant alkaloids are intensely bitter, bitter taste warns animals of potentially hazardous foods. To investigate the mechanism of bitter taste transduction, a preparation of dissociated rat taste cells was developed that can be studied with techniques designed for single-cell measurements. Denatonium, a very bitter substance, caused a rise in the intracellular calcium concentration due to release from internal stores in a small subpopulation of taste cells. Thus, the transduction of bitter taste may occur via a receptor-second messenger mechanism leading to neurotransmitter release and may not involve depolarization-mediated calcium entry.

pred. No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.

A;Note: the authors translated the codon GAG for residues 138 and 172 as Gln
C;Comment: The G proteins are a family of guanine nucleotide-binding proteins that
ains. The beta and gamma chains, required for GTPase activity, appear to be common
rase; it is specific for each type of G protein.
C;Comment: In mammals, four distinct types of beta chain's have been found.
